

Prerequisites: Python 3.11+, Node.js 18+, MongoDB running locally on port 27017.

Terminal 1 — Backend

```
cd d:\weatherfish\src
```

```
python -m uvicorn backend.main:app --host 127.0.0.1 --port 8000
```

You should see:

```
[MongoDB] Connected to mongodb://localhost:27017
```

```
[Scheduler] Started — hourly weather generation enabled
```

```
INFO: Uvicorn running on http://127.0.0.1:8000
```

Terminal 2 — Frontend

```
cd d:\weatherfish\src\frontend
```

```
npm run dev
```

You should see:

```
VITE v6.x ready in ...ms
```

```
→ Local: http://localhost:5173/
```

Terminal 3 — MongoDB (if not running as a service)

```
mongod --dbpath "C:\data\db"
```

Open the app

```
http://localhost:5173
```

Verify everything is working

```
# Backend health
```

```
Invoke-RestMethod http://127.0.0.1:8000/api/status
```

```
# Should show: mongodb=connected, snapshots=3, reports=3
```

First-time use (empty database)

1. Open `http://localhost:5173`
2. Type a PLZ (e.g. 20457) and city (e.g. Hamburg) → click +
3. Wait ~30 seconds while weather is fetched and report is generated
4. All cards populate automatically

If you already have locations saved, click  **Alle aktualisieren** to refresh all data.

Environment variables

Make sure `d:\weatherfish\src\.env` exists with:

`GEMINI_API_KEY=your_key`

`OPENWEATHER_API_KEY=your_key`

`MONGODB_URI=mongodb://localhost:27017`

The backend loads `.env` automatically on startup.
